PROJECT REPORT

Name - Chhavi Sharma

Registration Number - 25BCE10242

Project Topic - House Price Predictor

Language Used – Python

Introduction:

It is a system which tells about the price of a house based on the space, number of bedrooms and timespan of the house.

1.The problem - It is a problem of predicting the rate of a house on the basis of space, number of bedrooms and timespan of the house.

2.Importance - The House Price Predictor helps to automatically predict the price of the house with the help of simple calculation.

3.Solution of the problem - The steps needed to predict the price of the house are:

1. Import 'pandas' and 'Linear Regression'.
2. Enter the details about the house such as space, number of bedrooms, timespan and the rate of the house in dictionary.
3. Convert the data in tabular form using 'pd.DataFrame()'.
4. Separate input(X)data and output(Y)data.
5. Formula used = $\text{rate} = w1.\text{space} + w2.\text{bedrooms} + w3.\text{timespan} + b$
6. Train function and then find $w1, w2, w3, .$
7. Take inputs from user such as space, bedrooms, timespan.
8. Use rate predictor 'model.predict()' to predict the price of house.
9. Print the price, roundoff the digits to 4 decimal places and use lakhs as the unit of measurements.

4.Challenges faced -

- 1.Feeding details correctly.
- 2.Taking correct data from the users.
- 3.Calculating the price of the house using the formula.

5.Learning and Key takeaways -

- 1.Donot write useless codes.
- 2.Add comments to the code to make it more easily understandable.
- 3.Use libraries and formula for easy coding and calculations.
